

DAXPY (*Double precision- real Alpha X Plus Y*)

➤ Unidades funcionales (UF):

- 1 unidad de carga (instrucción (1)) segmentada en 2 etapas de 1 ciclo cada etapa,
- 1 unidad para almacenamiento (inst. (7)) de 0 ciclos,
- 2 unidades ALU para enteros (addl, addq, cmpl) de 1 ciclo,
- 1 unidad para mulpd de segmentada en 4 etapas de 1 ciclo cada etapa,
- 1 unidad para addpd segmentada en 2 etapas de 1 ciclo cada etapa, y
- 1 unidad de saltos (jb) de 1 ciclo en la etapa de ejecución.

```
for (i=0; i<N; i++) {  
    y[i]=a*x[i]+y[i];  
}
```

➤ Se captan, decodifican, emiten y se retiran del ROB 4 instrucciones ciclo.

- ROB: Entrada - registro renombrado – operando - validez del operando – marca(i,x,f)) – flush
- Se pueden captar junto a una instrucción de salto las instrucciones a ejecutar según la predicción del salto.

➤ Hay 5 etapas: captación (IF), decodificación+emisión (ID), envío a UF (E), ejecución (EX) y terminación del procesamiento (W). Todas las etapas consumen 1 ciclo de reloj, excepto EX cuyo consumo dependerá de la instrucción.

➤ Los valores de los registros están disponibles (válidos) al comienzo del procesamiento.

➤ Estación de reserva centralizada:

- La etapa ID (decodificación+emisión) emite instrucciones a la estación de reserva
- La etapa E (envío a UF) puede enviar a ejecutar instrucciones que tienen todos sus operandos disponibles. No puede enviar dos instrucciones en el mismo ciclo a la misma unidad funcional.

ROB y ventana de instruccio centralizada. Envío desorden

```
...
for (i=0; i<N; i++) {
    y[i]=a*x[i]+y[i];
}
...
```

T_{CPU} , CPI

$$T_{CPU} = NI \times CPI \times T_{ciclo} = 18 \times T_{ciclo}$$

$$CPI = \frac{\text{ciclos}}{\text{instrucciones}} = \frac{18}{20} = 0.9$$

$$\begin{aligned} T_{CPU}(n \text{ instr.}) &= 18 \times T_{ciclo} = T_{\text{LatenciaPrimeraInstr}} + T_{\text{RestoInstr}} \\ &= 6 \times T_{ciclo} + (20 - 1) \times CPI \times T_{ciclo} \end{aligned}$$

$$CPI = \frac{\text{ciclos}}{\text{instrucciones}} = \frac{18 - 6}{20 - 1} \approx 0.63$$
